

### FEATURES

- Stable over time and temperature
  - 0.5% initial accuracy
  - 1% accuracy over the full temperature range
- Compatible with Type II or Type III compensation networks
- Reference voltage: 1.225 V
- Compatible with DOSA
- Low power operation: <7 mA total
- Wide voltage supply range
  - V<sub>DD1</sub>: 3 V to 20 V
  - V<sub>DD2</sub>: 3 V to 20 V
- Bandwidth: 400 kHz
- Isolation voltage: 2.5 kV rms
- Safety and regulatory approvals (pending)
  - UL recognition: 2500 V rms for 1 minute per UL 1577
  - CSA Component Acceptance Notice #5A
  - VDE certificate of conformity
    - DIN V VDE V 0884-10 (VDE V 0884-10):2006-12
    - V<sub>IORM</sub> = 560 V peak
- Wide temperature range
  - 40°C to +125°C ambient operation
  - 150°C maximum junction temperature

### APPLICATIONS

- Linear power supplies
- Inverters
- Uninterruptible Power Supply (UPS)
- DOSA-compatible modules
- Voltage monitors

### GENERAL DESCRIPTION

The ADuM3190<sup>1</sup> is an isolated error amplifier based on Analog Devices, Inc., iCoupler® technology. The ADuM3190 is ideal for linear feedback power supplies. The primary side controllers of the ADuM3190 enable improvements in transient response, power density, and stability as compared to commonly used optocoupler and shunt regulator solutions.

Unlike optocoupler-based solutions, which have an uncertain current transfer ratio over lifetime and at high temperatures, the ADuM3190 transfer function does not change over its lifetime and it is stable over a wide temperature range of -40°C to +125°C.

Included in the ADuM3190 is a wideband operational amplifier for a variety of commonly used power supply loop compensation techniques. The ADuM3190 is fast enough to allow a feedback loop to react to fast transient conditions and overcurrent conditions. Also included is a high accuracy 1.225 V reference to compare with the supply output setpoint.

The ADuM3190 is packaged in a small 16-lead QSOP package for a 2.5 kV rms isolation voltage rating.

DC Voltage	1131	V peak	50-year minimum lifetime

<sup>1</sup> Refers to continuous voltage magnitude imposed across the isolation barrier. See the Insulation Lifetime section for more details.

**ESD CAUTION**

**ESD (electrostatic discharge) sensitive device.** Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

## PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

NC = NO CONNECTION. CONNECT PIN 5 TO GND<sub>1</sub>;  
DO NOT LEAVE THIS PIN FLOATING.

11335-005

Figure 3. Pin Configuration

Table 9. Pin Function Descriptions

Pin No.	Mnemonic	Description
1	V <sub>DD1</sub>	Supply Voltage for Side 1 (3.0 V to 20 V). Connect a 1 $\mu$ F capacitor between V <sub>DD1</sub> and GND <sub>1</sub> .
2	GND <sub>1</sub>	Ground Reference for Side 1.
3	V <sub>REG1</sub>	Internal Supply Voltage for Side 1. Connect a 1 $\mu$ F capacitor between V <sub>REG1</sub> and GND <sub>1</sub> .
4	REF <sub>OUT1</sub>	Reference Output Voltage for Side 1. The maximum capacitance for this pin (C <sub>REFOUT1</sub> ) must not exceed 15 pF.
5	NC	No Connection. Connect Pin 5 to GND <sub>1</sub> ; do not leave this pin floating.
6	EA <sub>OUT2</sub>	Isolated Output Voltage 2, Open-Drain Output. Connect a pull-up resistor between EA <sub>OUT2</sub> and V <sub>DD1</sub> for current up to 1 mA.
7	EA <sub>OUT</sub>	Isolated Output Voltage.
8	GND <sub>1</sub>	Ground Reference for Side 1.
9	GND <sub>2</sub>	Ground Reference for Side 2.
10	COMP	Output of the Op Amp. A loop compensation network can be connected between the COMP pin and the -IN pin.
11	-IN	Inverting Op Amp Input. Pin 11 is the connection for the power supply setpoint and compensation network.
12	+IN	Noninverting Op Amp Input. Pin 12 can be used as a reference input.
13	REF <sub>OUT</sub>	Reference Output Voltage for Side 2. The maximum capacitance for this pin (C <sub>REFOUT</sub> ) must not exceed 15 pF.
14	V <sub>REG2</sub>	Internal Supply Voltage for Side 2. Connect a 1 $\mu$ F capacitor between V <sub>REG2</sub> and GND <sub>2</sub> .
15	GND <sub>2</sub>	Ground Reference for Side 2.
16	V <sub>DD2</sub>	Supply Voltage for Side 2 (3.0 V to 20 V). Connect a 1 $\mu$ F capacitor between V <sub>DD2</sub> and GND <sub>2</sub> .

## APPLICATIONS INFORMATION

### THEORY OF OPERATION

In the test circuits of the ADuM3190 (see Figure 18 through Figure 20), external supply voltages from 3 V to 20 V are provided to the  $V_{DD1}$  and  $V_{DD2}$  pins, and internal regulators provide 3.0 V to operate the internal circuits of each side of the ADuM3190. An internal precision 1.225 V reference provides the reference for the  $\pm 1\%$  accuracy of the isolated error amplifier. UVLO circuits monitor the  $V_{DDx}$  supplies to turn on the internal circuits when the 2.8 V rising threshold is met and to turn off the error amplifier outputs to a high impedance state when  $V_{DDx}$  falls below 2.6 V.

The op amp on the right side of the device has a noninverting +IN pin and an inverting -IN pin available for connecting a feedback voltage in an isolated dc-to-dc converter output, usually through a voltage divider. The COMP pin is the op amp output, which can be used to attach resistor and capacitor components in a compensation network. The COMP pin internally drives the Tx transmitter block, which converts the op amp output voltage into an encoded output that is used to drive the digital isolator transformer.

On the left side of the ADuM3190, the transformer output PWM signal is decoded by the Rx block, which converts the signal into a voltage that drives an amplifier block; the amplifier block produces the error amplifier output available at the EA<sub>OUT</sub> pin. The EA<sub>OUT</sub> pin can deliver  $\pm 3$  mA and has a voltage level between 0.4 V and 2.4 V, which is typically used to drive the input of a PWM controller in a dc-to-dc circuit.

For applications that need more output voltage to drive their controllers, Figure 19 illustrates the use of the EA<sub>OUT2</sub> pin output which delivers up to  $\pm 1$  mA with an output voltage of 0.6 V to 4.8 V for an output that has a pull-up resistor to a 5 V supply. If the EA<sub>OUT2</sub> pull-up resistor connects to a 10 V to 20 V supply, the output is specified to a minimum of 5.0 V to allow use with a PWM controller requiring a minimum input operation of 5 V.

### ACCURACY CIRCUIT OPERATION

See Figure 18 and Figure 19 for stability of the accuracy circuits. The op amp on the right side of the ADuM3190, from the -IN pin to the COMP pin, has a unity-gain bandwidth (UGBW) of 10 MHz. Figure 21, Bode Plot 1, shows a dashed line for the op amp alone and its 10 MHz pole.

Figure 21 also shows the linear isolator alone (the blocks from the op amp output to the ADuM3190 output, labeled as the linear isolator), which introduces a pole at approximately 400 kHz. This total Bode plot of the op amp and linear isolator shows that the phase shift is approximately  $-180^\circ$  from the -IN pin to the EA<sub>OUT</sub> pin before the crossover frequency. Because a  $-180^\circ$  phase shift can make the system unstable, adding an integrator configuration, as shown in the test circuits in Figure 18 and Figure 19, consisting of a 2.2 nF capacitor and a 680  $\Omega$  resistor, helps to make the system stable. In Figure 22, Bode Plot 2 with an integrator configuration added, the system crosses over 0 dB at

approximately 100 kHz, but the circuit is more stable with a phase shift of approximately  $-120^\circ$ , which yields a stable  $60^\circ$  phase margin.

This circuit is used for accuracy tests only, not for real-world applications, because it has a 680  $\Omega$  resistor across the isolation barrier to close the loop for the error amplifier; this resistor causes leakage current to flow across the isolation barrier. For this test circuit only, GND<sub>1</sub> must be connected to GND<sub>2</sub> to create a return for the leakage current created by the 680  $\Omega$  resistor connection.

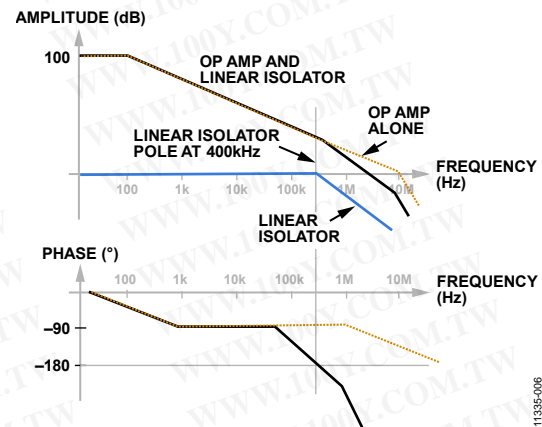

Figure 21. Bode Plot 1

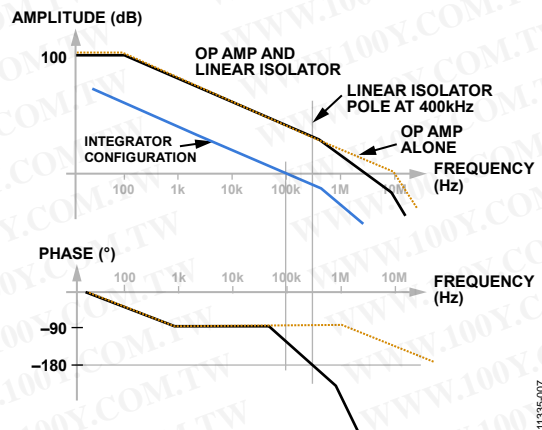

Figure 22. Bode Plot 2

### APPLICATION BLOCK DIAGRAM

Figure 23 shows a typical application, an isolated error amplifier in primary side control, for the ADuM3190. The op amp of the ADuM3190 is used as the error amplifier for the feedback of the output voltage,  $V_{OUT}$ , using a resistor divider to the -IN pin of the op amp. This configuration inverts the output signal at the COMP pin when compared to the +IN pin, which is connected to the internal 1.225 V reference. For example, when the output voltage,  $V_{OUT}$ , falls due to a load step, the divider voltage at the -IN pin falls below the +IN reference voltage, causing the COMP pin output signal to go high. The COMP output of the op amp is encoded and then decoded back by the digital isolator transformer block to a signal that drives the output of the ADuM3190

high. The output of the ADuM3190 drives the COMP pin of the PWM controller, which is designed to reset the PWM latch output to low only when its COMP pin is low. A high at the COMP pin has the effect of making the latching PWM comparator produce a PWM duty cycle output. This PWM duty cycle output drives the power stage to increase the V<sub>OUT</sub> voltage until it returns to regulation.

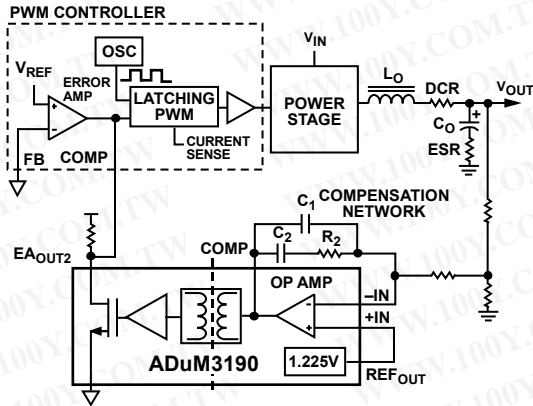

Figure 23. Application Block Diagram 1

The power stage output is filtered by output capacitance and, in some applications, by an inductor. Various elements contribute to the gain and phase of the control loop and the resulting stability. The Output Filter L and Output Filter C components create a double pole; the op amp has a pole at 10 MHz (see Figure 21), and the linear isolator has a pole at 400 kHz (see Figure 21 and Figure 22).

The output capacitor and its ESR can add a zero at a frequency that is dependent on the component type and values. With the ADuM3190 providing the error amplifier, a compensation network is provided from the -IN pin to the COMP pin to compensate the control loop for stability. The compensation network values depend on both the application and the components that are selected; information about the component network values is provided in the data sheet of the selected PWM controller.

The ADuM3190 has two different error amplifier outputs, EA<sub>OUT</sub> and EA<sub>OUT2</sub>. The EA<sub>OUT</sub> output, which can drive ±3 mA, has a guaranteed maximum high output voltage of at least 2.4 V, which may not be enough to drive the COMP pin of some PWM controllers. The EA<sub>OUT2</sub> pin can drive ±1 mA and has an output range that guarantees 5.0 V for a V<sub>DD1</sub> voltage range of 10 V to 20 V, which works well with the COMP pin of many PWM controllers.

In an application where the 5 V minimum output of the EA<sub>OUT2</sub> pin is not enough to drive the COMP pin of some PWM controllers, for example, controllers that operate with 6 V or more of COMP pin voltage, use EA<sub>OUT2</sub> to drive the FB pin of the error amplifier of the PWM controller (see Figure 24). The typical V<sub>REF</sub> voltage level of PWM controllers is approximately 1.25 V or 2.5 V, setting the reference level for the FB pin. In Figure 24, the

EA<sub>OUT2</sub> output is used for a PWM controller with a 2.5 V reference.

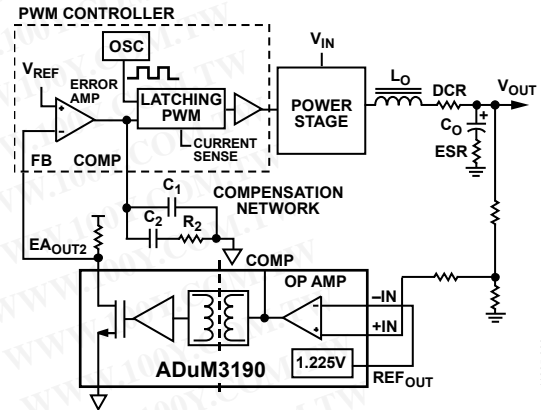

Figure 24. Application Block Diagram 2

As shown in Figure 24, the ADuM3190 op amp has the feedback voltage from the V<sub>OUT</sub> output divider is connected to the +IN pin, and the +1.225 V reference voltage connected to the -IN pin. This configuration produces a low going ADuM3190 COMP pin when the V<sub>OUT</sub> voltage drops from a load step. The EA<sub>OUT2</sub> pin follows the COMP pin, going low and connecting to the PWM controller FB pin. The error amplifier of the PWM controller has a reference (V<sub>REF</sub>) at the noninverting input, which, when the FB pin is low, makes the COMP pin of the error amplifier output go high. A high at the COMP pin causes the latching PWM comparator to produce a PWM duty cycle output. This PWM duty cycle output drives the power stage to increase the V<sub>OUT</sub> voltage until it returns to regulation.

The application block diagrams (see Figure 23 and Figure 24) show two different ways to use the ADuM3190 to provide isolated feedback in the control loop of an isolated dc-to-dc converter. In both figures, the loop is closed at approximately the 1.225 V reference voltage, providing ±1% accuracy over temperature. The ADuM3190 op amp has a high gain bandwidth of 10 MHz to allow the dc-to-dc converter to operate at high switching speeds, enabling smaller values for the Output Filter L and Output Filter C components.

The 400 kHz bandwidth of the ADuM3190 error amplifier output offers faster loop response for better transient response than the typical shunt regulator and optocoupler solutions, which typically have bandwidths of only 25 kHz to 50 kHz maximum.

### SETTING THE OUTPUT VOLTAGE

The output voltage in the application circuit can be set with two resistors in a voltage divider, as shown in Figure 25.

The output voltage is determined by the following equation, where V<sub>REF</sub> = 1.225 V:

$$V_{OUT} = V_{REF} \times (R_1 + R_2)/R_2 \tag{1}$$

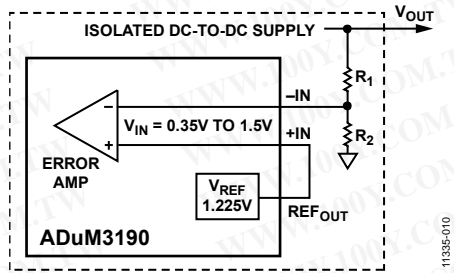

Figure 25. Setting the Output Voltage

**DOSA MODULE APPLICATION**

Figure 26 is a block diagram of a Distributed-power Open Standards Alliance (DOSA) circuit using the ADuM3190. The block diagram shows how to use the ADuM3190 1.225 V reference and the error amp in a DOSA standard power supply module circuit to produce output voltage settings using a combination of resistors.

The ADuM3190 1.225 V reference is specified for ±1% over the -40°C to +125°C temperature range. See Table 10 to select the resistor values to set the output voltage of the module. Two different ranges of VOUT can be implemented, VOUT > 1.5 V or VOUT < 1.5 V, depending on the required module.

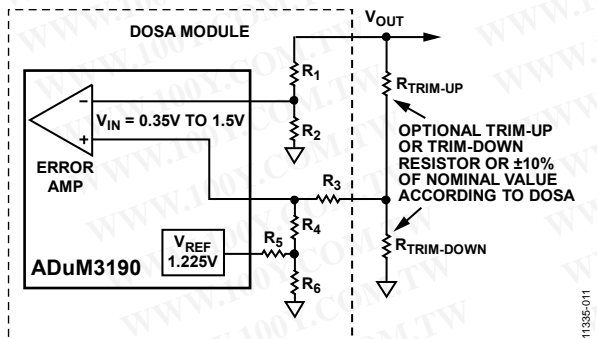

Figure 26. DOSA Module

**Table 10. Resistor Values for DOSA Module**

Module Nominal Output	R3	R4	R5	R6
VOUT > 1.5 V	1 kΩ	1 kΩ	0 Ω	Open
VOUT < 1.5 V	1 kΩ	0 Ω	2.05 kΩ	1.96 kΩ
VOUT > 1.5 V	5.11 kΩ	5.11 kΩ	0 Ω	Open
VOUT < 1.5 V	5.11 kΩ	0 Ω	10.5 kΩ	10.0 kΩ

**DC CORRECTNESS AND MAGNETIC FIELD IMMUNITY**

Positive and negative logic transitions at the isolator input cause narrow (~1 ns) pulses to be sent to the decoder via the transformer. The decoder is bistable and is, therefore, either set or reset by the pulses, indicating input logic transitions. In the absence of logic transitions of more than 1 μs at the input, a periodic set of refresh pulses indicative of the correct input state are sent to ensure dc correctness at the output.

If the decoder receives no internal pulses for more than approximately 3 μs, the input side is assumed to be unpowered or nonfunctional, in which case, the isolator output is forced to

a default high impedance state by the watchdog timer circuit. In addition, the outputs are in a default high impedance state while the power is increasing before the UVLO threshold is crossed.

The ADuM3190 is immune to external magnetic fields. The limitation on the ADuM3190 magnetic field immunity is set by the condition whereby induced voltage in the transformer receiving coil is sufficiently large to either falsely set or reset the decoder. The following analysis defines the conditions under which this can occur. The 3 V operating condition of the ADuM3190 is examined because it represents the most susceptible mode of operation. The pulses at the transformer output have an amplitude that is greater than 1.0 V. The decoder has a sensing threshold at approximately 0.5 V, therefore establishing a 0.5 V margin within which induced voltages are tolerated. The voltage induced across the receiving coil is given by

$$V = (-d\beta/dt) \sum \pi r_n^2, n = 1, 2, \dots, N$$

where:

β is the magnetic flux density (gauss).

r<sub>n</sub> is the radius of the nth turn in the receiving coil (cm).

N is the number of turns in the receiving coil.

Given the geometry of the receiving coil in the ADuM3190 and an imposed requirement that the induced voltage be, at most, 50% of the 0.5 V margin at the decoder, a maximum allowable magnetic field is calculated, as shown in Figure 27.

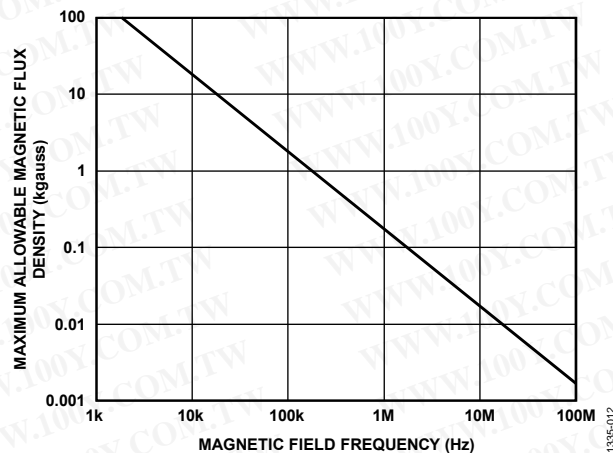

Figure 27. Maximum Allowable External Magnetic Flux Density

For example, at a magnetic field frequency of 1 MHz, the maximum allowable magnetic field of 0.02 kgauss induces a voltage of 0.25 V at the receiving coil. This is approximately 50% of the sensing threshold and does not cause a faulty output transition. Similarly, if such an event were to occur during a transmitted pulse (and had the worst-case polarity), the received pulse is reduced from >1.0 V to 0.75 V, still well above the 0.5 V sensing threshold of the decoder.

The preceding magnetic flux density values correspond to specific current magnitudes at given distances away from the ADuM3190 transformers. Figure 28 shows these allowable current magnitudes as a function of frequency for selected distances. As shown Figure 28, the ADuM3190 is immune and can

be affected only by extremely large currents operating at a high frequency very close to the component. For the 1 MHz example, a 0.7 kA current must be placed 5 mm away from the ADuM3190 to affect the operation of the device.

Figure 28. Maximum Allowable Current for Various Current-to-ADuM3190 Spacings

**INSULATION LIFETIME**

All insulation structures eventually break down when subjected to voltage stress over a sufficiently long period. The rate of insulation degradation is dependent on the characteristics of the voltage waveform applied across the insulation. In addition to the testing performed by the regulatory agencies, Analog Devices carries out an extensive set of evaluations to determine the lifetime of the insulation structure within the ADuM3190.

Analog Devices performs accelerated life testing using voltage levels higher than the rated continuous working voltage. Acceleration factors for several operating conditions are determined. These factors allow calculation of the time to failure at the actual working voltage.

The values shown in Table 8 summarize the peak voltage for 50 years of service life for a bipolar ac operating condition. In many cases, the approved working voltage is higher than the 50-year service life voltage. Operation at these high working voltages can lead to shortened insulation life in some cases.

The ADuM3190 insulation lifetime depends on the voltage waveform type imposed across the isolation barrier. The iCoupler insulation structure degrades at different rates depending on whether the waveform is bipolar ac, unipolar ac, or dc. Figure 29, Figure 30, and Figure 31 illustrate these different isolation voltage waveforms.

A bipolar ac voltage environment is the worst case for the iCoupler products yet meets the 50-year operating lifetime recommended by Analog Devices for maximum working voltage. In the case of unipolar ac or dc voltage, the stress on the insulation is significantly lower. This allows operation at higher working voltages while still achieving a 50-year service life. Treat any cross-insulation voltage waveform that does not conform to Figure 30 or Figure 31 as a bipolar ac waveform, and limit its peak voltage to the 50-year lifetime voltage value listed in Table 8.

Note that the voltage presented in Figure 30 is shown as sinusoidal for illustration purposes only. It is meant to represent any voltage waveform varying between 0 V and some limiting value. The limiting value can be positive or negative, but the voltage cannot cross 0 V.
