## General Description

The MAX6369－MAX6374 are pin－selectable watchdog timers that supervise microprocessor（ $\mu \mathrm{P}$ ）activity and signal when a system is operating improperly．During normal operation，the microprocessor should repeated－ ly toggle the watchdog input（WDI）before the selected watchdog timeout period elapses to demonstrate that the system is processing code properly．If the $\mu \mathrm{P}$ does not provide a valid watchdog input transition before the timeout period expires，the supervisor asserts a watch－ dog（ $\overline{\mathrm{WDO})}$ output to signal that the system is not exe－ cuting the desired instructions within the expected time frame．The watchdog output pulse can be used to reset the $\mu \mathrm{P}$ or interrupt the system to warn of processing errors．
The MAX6369－MAX6374 are flexible watchdog timer supervisors that can increase system reliability through notification of code execution errors．The family offers several pin－selectable watchdog timing options to match a wide range of system timing applications：
－Watchdog startup delay：provides an initial delay before the watchdog timer is started．
－Watchdog timeout period：normal operating watch－ dog timeout period after the initial startup delay．
－Watchdog output／timing options：open drain（100ms） or push－pull（1ms）
The MAX6369－MAX6374 operate over a +2.5 V to +5.5 V supply range and are available in miniature 8－pin SOT23 packages．

# Pin-Selectable Watchdog Timers 

Pin Description

| PIN | NAME | FUNCTION |
| :---: | :---: | :---: |
| 1 | WDI | Watchdog Input. If WDI remains either high or low for the duration of the watchdog timeout period (twD), $\overline{\text { WDO }}$ triggers a pulse. The internal watchdog timer clears whenever a $\overline{\mathrm{WDO}}$ is asserted or whenever WDI sees a rising or falling edge. |
| 2 | GND | Ground |
| 3 | N.C. | Not Connected. Do not make any connection to this pin. |
| 4 | SETO | Set Zero. Logic input for selecting startup delay and watchdog timeout periods. See Table 1 for timing details. |
| 5 | SET1 | Set One. Logic input for selecting startup delay and watchdog timeout periods. See Table 1 for timing details. |
| 6 | SET2 | Set Two. Logic input for selecting startup delay and watchdog timeout periods. See Table 1 for timing details. |
| 7 | $\overline{\text { WDO }}$ | Watchdog Output. Pulses low for the watchdog output pulse width, twDO, when the internal watchdog times out. The MAX6369/MAX6371/MAX6373 have open-drain outputs and require a pull-up resistor. The MAX6370/MAX6372/MAX6374 outputs are push-pull. |
| 8 | VCC | Supply Voltage ( +2.5 V to +5.5 V ) |

## Detailed Description

The MAX6369-MAX6374 are flexible watchdog circuits for monitoring $\mu \mathrm{P}$ activity. During normal operation, the internal timer is cleared each time the $\mu \mathrm{P}$ toggles the WDI with a valid logic transition (low to high or high to low) within the selected timeout period (twD). The WDO remains high as long as the input is strobed within the selected timeout period. If the input is not strobed before the timeout period expires, the watchdog output is asserted low for the watchdog output pulse width (tWDO). The device type and the state of the three logic control pins (SETO, SET1, and SET2) determine watchdog timing characteristics. The three basic timing variations for the watchdog startup delay and the normal
watchdog timeout period are summarized below (see Table 1 for the timeout characteristics for all devices in the family):

- Watchdog Startup Delay:

Provides an initial delay before the watchdog timer is started.
Allows time for the $\mu \mathrm{P}$ system to power up and initialize before assuming responsibility for normal watchdog timer updates.
Includes several fixed or pin-selectable startup delay options from $200 \mu \mathrm{~s}$ to 60 s , and an option to wait for the first watchdog input transition before starting the watchdog timer.

## MAX6369-MAX6374 <br> Pin-Selectable Watchdog Timers

Figure 1. Functional Diagram

Figure 2. Watchdog Timing

- Watchdog Timeout Period:

Normal operating watchdog timeout period after the initial startup delay.
A watchdog output pulse is asserted if a valid watchdog input transition is not received before the timeout period elapses.
Eight pin-selectable timeout period options for each device, from $30 \mu \mathrm{~s}$ to 60 s .
Pin-selectable watchdog timer disable feature.

- Watchdog Output/Timing Options:

Open drain, active low with 100 ms minimum watchdog output pulse (MAX6369/MAX6371/MAX6373).
Push-pull, active low with 1 ms minimum watchdog output pulse (MAX6370/MAX6372/MAX6374).
Each device has a watchdog startup delay that is initiated when the supervisor is first powered or after the user modifies any of the logic control set inputs. The watchdog timer does not begin to count down until the

## MAX6369-MAX6374

## Pin-Selectable Watchdog Timers

completion of the startup delay period, and no watchdog output pulses are asserted during the startup delay. When the startup delay expires, the watchdog begins counting its normal watchdog timeout period and waiting for WDI transitions. The startup delay allows time for the $\mu \mathrm{P}$ system to power up and fully initialize before assuming responsibility for the normal watchdog timer updates. Startup delay periods vary between the different devices and may be altered by the logic control set pins. To ensure that the system generates no undesired watchdog outputs, the routine watchdog input transitions should begin before the selected minimum startup delay period has expired.
The normal watchdog timeout period countdown is initiated when the startup delay is complete. If a valid logic transition is not recognized at WDI before the watchdog timeout period has expired, the supervisor asserts a watchdog output. Watchdog timeout periods vary between the different devices and may be altered by the logic control set pins. To ensure that the system generates no undesired watchdog outputs, the watchdog input transitions should occur before the selected minimum watchdog timeout period has expired.
The startup delay and the watchdog timeout period are determined by the states of the SETO, SET1, and SET2 pins, and by the particular device within the family. For the MAX6369 and MAX6370, the startup delay is equal to the watchdog timeout period. The startup and watchdog timeout periods are pin selectable from 1 ms to 60s (minimum).
For the MAX6371 and MAX6372, the startup delay is fixed at 60s and the watchdog timeout period is pin selectable from 1ms to 60s (minimum).
The MAX6373/MAX6374 provide two timing variations for the startup delay and normal watchdog timeout. Five of the pin-selectable modes provide startup delays from $200 \mu$ s to 60 s minimum, and watchdog timeout
delays from 3 ms to 10 s minimum. Two of the selectable modes do not initiate the watchdog timer until the device receives its first valid watchdog input transition (there is no fixed period by which the first input must be received). These two extended startup delay modes are useful for applications requiring more than 60 s for system initialization.
All the MAX6369-MAX6374 devices may be disabled with the proper logic control pin setting (Table 1).

## Applications Information

## Input Signal Considerations

Watchdog timing is measured from the last WDI rising or falling edge associated with a pulse of at least 100ns in width. WDI transitions are ignored when WDO is asserted, and during the startup delay period (Figure 2). Watchdog input transitions are also ignored for a setup period, tSETUP, of up to $300 \mu$ s after power-up or a setting change (Figure 3).

## Selecting Device Timing

SET2, SET1, and SET0 program the startup delay and watchdog timeout periods (Table 1). Timeout settings can be hard wired, or they can be controlled with logic gates and modified during operation. To ensure smooth transitions, the system should strobe WDI immediately before the timing settings are changed. This minimizes the risk of initializing a setting change too late in the timer countdown period and generating undesired watchdog outputs. After changing the timing settings, two outcomes are possible based on $\overline{W D O}$. If the change is made while $\overline{W D O}$ is asserted, the previous setting is allowed to finish, the characteristics of the new setting are assumed, and the new startup phase is entered after a $300 \mu$ s setup time (tSETUP) elapses. If the change is made while $\overline{W D O}$ is not asserted, the new setting is initiated immediately, and the new startup phase is entered after the $300 \mu$ s setup time elapses.

Figure 3. Setting Change Timing

## MAX6369-MAX6374

## Pin-Selectable Watchdog Timers

Figure 4. Watchdog Flow Diagram

Selecting 011 (SET2 = 0, SET1 = 1, SET0 = 1) disables the watchdog timer function on all devices in the family. Operation can be reenabled without powering down by changing the set inputs to the new desired setting. The device assumes the new selected timing characteristics and enter the startup phase after the $300 \mu$ s setup time elapses (Figure 3). $\overline{W D O}$ is high when the watchdog timer is disabled.
The MAX6373/MAX6374 offer a first-edge feature. In first-edge mode (settings 101 or 110, Table 1), the internal timer does not control the startup delay period. Instead, startup terminates when WDI sees a transition. If changing to first-edge mode while the device is operating, disable mode must be entered first. It is then safe to select first-edge mode. Entering disable mode first ensures the output is unasserted when selecting firstedge mode and removes the danger of WDI being masked out.

## Output

The MAX6369/MAX6371/MAX6373 have an active-low, open-drain output that provides a watchdog output pulse of 100 ms . This output structure sinks current when WDO is asserted. Connect a pullup resistor from $\overline{\mathrm{WDO}}$ to any supply voltage up to +5.5 V .
Select a resistor value large enough to register a logic low (see Electrical Characteristics), and small enough to register a logic high while supplying all input current and leakage paths connected to the WDO line. A $10 \mathrm{k} \Omega$ pullup is sufficient in most applications. The MAX6370/ MAX6372/MAX6374 have push-pull outputs that provide an active-low watchdog output pulse of 1 ms . When WDO deasserts, timing begins again at the beginning of the watchdog timeout period (Figure 2).

## Usage in Noisy Environments

If using the watchdog timer in an electrically noisy environment, a bypass capacitor of $0.1 \mu \mathrm{~F}$ should be connected between VCC and GND as close to the device as possible, and no further away than 0.2 inches.

## Watchdog Software Considerations

To help the watchdog timer monitor software execution more closely, set and reset the watchdog input at different points in the program, rather than pulsing the watchdog input high-low-high or low-high-low. This technique avoids a stuck loop, in which the watchdog timer would continue to be reset inside the loop, keeping the watchdog from timing out. Figure 4 shows an example of a flow diagram where the I/O driving the watchdog input is set high at the beginning of the program, set low at the end of every subroutine or loop, then set high again when the program returns to the beginning. If the program should hang in any subroutine, the problem would be quickly corrected, since the I/O is continually set low and the watchdog timer is allowed to time out, causing $\overline{\mathrm{WDO}}$ to pulse.
