# Low－Power，Quad，10－Bit Voltage－Output DAC with Serial Interface 

General Description
The＋5V MAX5250 combines four low－power，voltage－ output，10－bit digital－to－analog converters（DACs）and four precision output amplifiers in a space－saving，20－ pin package．In addition to the four voltage outputs， each amplifier＇s negative input is also available to the user．This facilitates specific gain configurations，remote sensing，and high output drive capacity，making the MAX5250 ideal for industrial－process－control applica－ tions．Other features include software shutdown，hard－ ware shutdown lockout，an active－low reset that clears all registers and DACs to zero，a user－programmable logic output，and a serial－data output．
Each DAC has a double－buffered input organized as an input register followed by a DAC register．A 16－bit serial word loads data into each input／DAC register．The 3 －wire serial interface is compatible with SPI ${ }^{\text {TM }} / Q S P I^{T M}$ and MICROWIRE ${ }^{\text {TM }}$ ．It allows the input and DAC regis－ ters to be updated independently or simultaneously with a single software command．All logic inputs are TTL／CMOS－logic compatible．

## Applications

Digital Offset and Gain Adjustment Microprocessor－Controlled Systems Industrial Process Controls Automatic Test Equipment Remote Industrial Controls Motion Control

Features
－Four 10－Bit DACs with Configurable Output Amplifiers
－＋5V Single－Supply Operation
－Low Supply Current：0．85mA Normal Operation 10ヶA Shutdown Mode
－Available in 20－Pin SSOP and DIP Packages
－Power－On Reset Clears all Registers and DACs to Zero
－SPI／QSPI and MICROWIRE Compatible
－Simultaneous or Independent Control of DACs through 3－Wire Serial Interface
－User－Programmable Digital Output
－Schmitt－Trigger Inputs for Direct Optocoupler Interface
－12－Bit Upgrade Available：MAX525

# Low-Power, Quad, 10-Bit Voltage-Output DAC with Serial Interface 

Figure 1. Simplified DAC Circuit Diagram

## Detailed Description

The MAX5250 contains four 10-bit, voltage-output digi-tal-to-analog converters (DACs) that are easily addressed using a simple 3 -wire serial interface. It includes a 16 -bit data-in/data-out shift register, and each DAC has a doubled-buffered input composed of an input register and a DAC register (see Functional Diagram). In addition to the four voltage outputs, each amplifier's negative input is available to the user.
The DACs are inverted R-2R ladder networks that convert a digital input ( 10 data bits plus 2 sub-bits) into equivalent analog output voltages in proportion to the applied reference voltage inputs. DACs $A$ and $B$ share the REFAB reference input, while DACs $C$ and $D$ share the REFCD reference input. The two reference inputs allow different full-scale output voltage ranges for each pair of DACs. Figure 1 shows a simplified circuit diagram of one of the four DACs.

Reference Inputs
The two reference inputs accept positive DC and AC signals. The voltage at each reference input sets the full-scale output voltage for its two corresponding DACs. The reference input voltage range is OV to (VDD-1.4V). The output voltages (Vout_) are represented by a digitally programmable voltage source as:

$$
\text { Vout_ }=(\text { VREF } \times \text { NB } / 1024) \times \text { Gain }
$$

where NB is the numeric value of the DAC's binary input code ( 0 to 1023), VreF is the reference voltage, and Gain is the externally set voltage gain.

The impedance at each reference input is code dependent, ranging from a low value of $10 \mathrm{k} \Omega$ when both DACs connected to the reference have an input code of 554 hex, to a high value exceeding several giga ohms (leakage currents) with an input code of 000 hex. Because the input impedance at the reference pins is code dependent, load regulation of the reference source is important.
The REFAB and REFCD reference inputs have a $10 \mathrm{k} \Omega$ guaranteed minimum input impedance. When the two reference inputs are driven from the same source, the effective minimum impedance is $5 \mathrm{k} \Omega$. A voltage reference with a load regulation of $6 \mathrm{ppm} / \mathrm{mA}$, such as the MAX873, would typically deviate by 0.006 LSB ( 0.015 LSB worst case) when driving both MAX5250 reference inputs simultaneously at 2.5 V . Driving the REFAB and REFCD pins separately improves reference accuracy.
In shutdown mode, the MAX5250's REFAB and REFCD inputs enter a high-impedance state with a typical input leakage current of $0.01 \mu \mathrm{~A}$.
The reference input capacitance is also code dependent and typically ranges from 20pF with an input code of all Os to 100 pF at full scale.

Output Amplifiers
All MAX5250 DAC outputs are internally buffered by precision amplifiers with a typical slew rate of $0.6 \mathrm{~V} / \mathrm{\mu s}$. Access to each output amplifier's inverting input provides the user greater flexibility in output gain setting/ signal conditioning (see the Applications Information section).
With a full-scale transition at the MAX5250 output, the typical settling time to $\pm 1 / 2 \mathrm{LSB}$ is $10 \mu \mathrm{~s}$ when loaded with $5 \mathrm{k} \Omega$ in parallel with 100 pF (loads less than $2 \mathrm{k} \Omega$ degrade performance).
The MAX5250 output amplifier's output dynamic responses and settling performances are shown in the Typical Operating Characteristics.

Power-Down Mode
The MAX5250 features a software-programmable shutdown that reduces supply current to a typical value of 10 AA. The power-down lockout pin ( $\overline{\text { PDL }})$ must be high to enable shutdown mode. Writing 1100XXXXXXXXXXXX as the input-control word puts the MAX5250 in power-down mode (Table 1).

## Low-Power, Quad, 10-Bit Voltage-Output DAC with Serial Interface

In power-down mode, the MAX5250 output amplifiers and the reference inputs enter a high-impedance state. The serial interface remains active. Data in the input registers is retained in power-down, allowing the MAX5250 to recall the output states prior to entering shutdown. Start up from power-down either by recalling the previous configuration or by updating the DACs with new data. When powering up the device or bringing it out of shutdown, allow $15 \mu$ s for the outputs to stabilize.

## Serial-Interface Configurations

The MAX5250's 3-wire serial interface is compatible with both MICROWIRE (Figure 2) and SPI/QSPI (Figure 3). The serial input word consists of two address bits and two control bits followed by 10+2 data bits (MSB first), as shown in Figure 4. The 4-bit address/ control code determines the MAX5250's response outlined in Table 1. The connection between DOUT and the serial-interface port is not necessary, but may be used for data echo. Data held in the MAX5250's shift register can be shifted out of DOUT and returned to the microprocessor ( $\mu \mathrm{P}$ ) for data verification.
The MAX5250's digital inputs are double buffered. Depending on the command issued through the serial interface, the input register(s) can be loaded without affecting the DAC register(s), the DAC register(s) can be loaded directly, or all four DAC registers can be updated simultaneously from the input registers (Table 1).

## Serial-Interface Description

The MAX5250 requires 16 bits of serial data. Table 1 lists the serial-interface programming commands. For certain commands, the $10+2$ data bits are "don't cares." Data is sent MSB first and can be sent in two 8 -bit packets or one 16-bit word ( $\overline{\mathrm{CS}}$ must remain low until 16 bits are transferred). The serial data is composed of two DAC address bits (A1, A0) and two control bits (C1, C0), followed by the 10+2 data bits D9...D0, S1, S0 (Figure 4). Set both sub-bits (S1, S0) to zero. The 4-bit address/control code determines:

- The register(s) to be updated
- The clock edge on which data is to be clocked out through the serial-data output (DOUT)
- The state of the user-programmable logic output (UPO)
- If the part is to go into shutdown mode (assuming $\overline{P D L}$ is high)
- How the part is configured when coming out of shutdown mode.

*THE DOUT-SI CONNECTION IS NOT REQUIRED FOR WRITIIIG TO THE MAX5250, BUT CAN BE USED FOR READBACK PURPOSES.

| 1 | 0 |  | 0 | XXXXXXXXXX | X | X | Mode 0, DOUT clocked out on SCLK's falling edge. All DAC registers updated (default). |

" X " = Don't care

Figure 5 shows the serial-interface timing requirements. The chip-select pin ( $\overline{\mathrm{CS}}$ ) must be low to enable the DAC's serial interface. When $\overline{\mathrm{CS}}$ is high, the interface control circuitry is disabled. $\overline{\mathrm{CS}}$ must go low at least tcss before the rising serial clock (SCLK) edge to properly clock in the first bit. When $\overline{\mathrm{CS}}$ is low, data is clocked into the internal shift register through the serialdata input pin (DIN) on SCLK's rising edge. The maximum guaranteed clock frequency is 10 MHz . Data is latched into the appropriate MAX5250 input/DAC registers on CS's rising edge.
The programming command Load-All-DACs-From-ShiftRegister allows all input and DAC registers to be simultaneously loaded with the same digital code from the input shift register. The no operation (NOP) command leaves the register contents unaffected and is useful when the MAX5250 is configured in a daisy chain (see the Daisy Chaining Devices section). The command to
change the clock edge on which serial data is shifted out of DOUT also loads data from all input registers to their respective DAC registers.

## Serial-Data Output (DOUT)

The serial-data output, DOUT, is the internal shift register's output. The MAX5250 can be programmed so that data is clocked out of DOUT on SCLK's rising edge (Mode 1) or falling edge (Mode 0). In Mode 0, output data at DOUT lags input data at DIN by 16.5 clock cycles, maintaining compatibility with MICROWIRE, SPI/QSPI, and other serial interfaces. In Mode 1, output data lags input data by 16 clock cycles. On power-up, DOUT defaults to Mode 0 timing.

## User-Programmable Logic Output (UPO)

The user-programmable logic output, UPO, allows an external device to be controlled through the MAX5250 serial interface (Table 1).

## Low-Power, Quad, 10-Bit Voltage-Output DAC with Serial Interface

Figure 5. Serial-Interface Timing Diagram

Figure 6. Detailed Serial-Interface Timing Diagram

## Power-Down (PDL)

The power-down lockout pin PDL disables software shutdown when low. When in shutdown, transitioning PDL from high to low wakes up the part with the output set to the state prior to shutdown. $\overline{\mathrm{PDL}}$ can also be used to wake up the device asynchronously.

## Daisy Chaining Devices

Any number of MAX5250s can be daisy chained by connecting the DOUT pin of one device to the DIN pin of the following device in the chain (Figure 7).

Since the MAX5250's DOUT pin has an internal active pull-up, the DOUT sink/source capability determines the time required to discharge/charge a capacitive load. Refer to the serial-data-out VoH and Vol specifications in the Electrical Characteristics.

Figure 8 shows an alternate method of connecting several MAX5250s. In this configuration, the data bus is common to all devices; data is not shifted through a daisy chain. More I/O lines are required in this configuration because a dedicated chip-select input $(\overline{\mathrm{CS}})$ is required for each IC.

## Applications Information

## Unipolar Output

For a unipolar output, the output voltages and the reference inputs have the same polarity. Figure 9 shows the MAX5250 unipolar output circuit, which is also the typical operating circuit. Table 2 lists the unipolar output codes.
For rail-to-rail outputs, see Figure 10. This circuit shows the MAX5250 with the output amplifiers configured with a closed-loop gain of +2 to provide 0 V to 5 V full-scale range when a 2.5 V reference is used.

Bipolar Output
The MAX5250 outputs can be configured for bipolar operation using Figure 11's circuit:
VoUT = VREF [(2NB / 1024) - 1]
where NB is the numeric value of the DAC's binary input code. Table 3 shows digital codes (offset binary) and corresponding output voltages for Figure 11's circuit.

## Using an AC Reference

In applications where the reference has AC signal components, the MAX5250 has multiplying capability within the reference input range specifications. Figure 12 shows a technique for applying a sine-wave signal to the reference input where the AC signal is offset before being applied to REFAB/REFCD. The reference voltage must never be more negative than DGND.
The MAX5250's total harmonic distortion plus noise (THD $+N$ ) is typically less than -72 dB (full-scale code), given a 1VP-p signal swing and input frequencies up to 25 kHz . The typical -3 dB frequency is 650 kHz , as shown in the Typical Operating Characteristics graphs.

Digitally Programmable Current Source The circuit of Figure 13 places an NPN transistor (2N3904 or similar) within the op-amp feedback loop to implement a digitally programmable, unidirectional current source. This circuit can be used to drive $4-20 \mathrm{~mA}$ current loops, which are commonly used in industrialcontrol applications. The output current is calculated with the following equation:

$$
\text { IOUT }=(\text { VREF } / R) \times(N B / 1024)
$$

where $N B$ is the numeric value of the DAC's binary input code and $R$ is the sense resistor shown in Figure 13.

Figure 13. Digitally Programmable Current Source

Power-Supply Considerations
On power-up, all input and DAC registers are cleared (set to zero code) and DOUT is in Mode 0 (serial data is shifted out of DOUT on the clock's falling edge).
For rated MAX5250 performance, limit REFAB/REFCD to less than 1.4V below VDD. Bypass VDD with a $4.7 \mu \mathrm{~F}$ capacitor in parallel with a $0.1 \mu \mathrm{~F}$ capacitor to AGND. Use short lead lengths and place the bypass capacitors as close to the supply pins as possible.

## Grounding and Layout Considerations

Digital or AC transient signals between AGND and DGND can create noise at the analog outputs. Tie AGND and DGND together at the DAC, then tie this point to the highest-quality ground available.
Good printed circuit board ground layout minimizes crosstalk between DAC outputs, reference inputs, and digital inputs. Reduce crosstalk by keeping analog lines away from digital lines. Wire-wrapped boards are not recommended
