

Features

- Excellent differential gain and phase on $\pm 5V$ to $\pm 15V$ supplies
- 100 MHz -3 dB bandwidth from gains of ± 1 to ± 10
- 700 V/µs slew rate
- 0.1 dB flatness to 20 MHz
- Output disable in 50 ns remains high impedance even when driven with large slew rates
- Single + 5V supply operation
- AC characteristics are lot and temperature stable
- Available in small SO-8 package

Applications

- Video gain block
- Residue amplifier
- Multiplexer
- Current to voltage converter
- Coax cable driver with gain of 2
- ADC driver

General Description

The EL2120C is a wideband current feedback amplifier optimized for video performance. Its 0.01% differential gain and 0.03 degree differential phase performance when at \pm 5V supplies exceeds the performance of other amplifiers running on \pm 15V supplies. Operating on \pm 8 to \pm 15V supplies reduces distortions to 0.01% and 0.01 degrees and below. The EL2120C can operate with supplies as low as \pm 2.5V or a single \pm 5V supply.

Being a current feedback design, bandwidth is a relatively constant 100 MHz over the ± 1 to ± 10 gain range. The EL2120C has been optimized for flat gain over frequency and all characteristics are maintained at positive unity gain. Because the input slew rate is similar to the 700 V/ μ s output slew rate the part makes an excellent high-speed buffer.

The EL2120C has a superior output disable function. Time to enable or disable is 50 ns and does not change markedly with temperature. Furthermore, in disable mode the output does not draw excessive currents when driven with 1000 V/ μ s slew rates. The output appears as a 3 pF load when disabled.

Applications Information

The EL2120C represents the third generation of current-feedback amplifier design. It is designed to provide good high-frequency performance over wide supply voltage, load impedance, gain, temperature, and manufacturing lot variations. It is a well-behaved amplifier in spite of its 100 MHz bandwidth, but a few precautions should be taken to obtain maximum performance.

The power supply pins must be well bypassed. 0.01 μ F ceramic capacitors are adequate, but lead length should be kept below $\frac{1}{4}$ " and a ground plane is recommended. Bypassing with 4.7 μ F tantalum capacitors can improve settling characteristics, and smaller capacitors in parallel will not be needed. The lead length of sockets generally deteriorates the amplifier's frequency response by exaggerating peaking and increasing ringing in response to transients. Short sockets cause little degradation.

Load capacitance also increases ringing and peaking. Capacitance greater than 35 pF should be isolated with a series resistor. Capacitance at the V_{IN-} terminal has a similar effect, and should be kept below 5 pF. Often, the inductance of the leads of a load capacitance will be self-resonant at frequencies from 40 MHz to 200 MHz and can cause oscillations. A resonant load can be de-Q'ed with a small series or parallel resistor. A "snubber" can sometimes be used to reduce resonances. This is a resistor and capacitor in series connected from output to ground. Values of 68 Ω and 33 pF are typical. Increasing the feedback resistor can also improve frequency flatness.

The V_{IN+} pin can oscillate in the 200 MHz to 500 MHz realm if presented with a resonant or inductive source impedance. A series 27Ω to 68Ω resistor right on the V_{IN+} pin will suppress such oscillations without affecting frequency response.

-3 dB bandwidth is inversely proportional to the value of feedback resistor $R_F.$ The EL2120C will tolerate values as low as 180 Ω for a maximum bandwidth of about 140 MHz, but peaking will increase and tolerance to stray capacitance will reduce. At gains greater than 5, -3 dB bandwidth begins to reduce, and a smaller R_F can be used to maximize frequency response.

The greatest frequency response flatness (to 0.1 dB, for instance) occurs with $R_{\rm F}=300\Omega$ to $330\Omega.$ Even the moderate peaking caused by lower values of $R_{\rm F}$ will cause the gain to peak out of the 0.1 dB window, and higher values of $R_{\rm F}$ will cause an overcompensated response where the gain falls below the 0.1 dB level. Parasitic capacitances will generally degrade the frequency flatness.

The EL2120C should not output a continuous current above 50 mA, as stated in the ABSO-LUTE MAXIMUM RATINGS table. The output current limit is set to 120 mA at a die temperature of 25°C and reduces to 85 mA at a die temperature of 150°C. This large current is needed to slew load capacitance and drive low impedance loads with low distortion but cannot be supported continuously. Furthermore, package dissipation capabilities cannot be met under short-circuit conditions. Current limit should not occur longer than a few seconds.

The output disable function of the EL2120C is optimized for video performance. While in disable mode, the feedthrough of the circuit can be modeled as a 0.2 pF capacitor from V_{IN+} to the output. No more than $\pm 5V$ can be placed between V_{IN+} and V_{IN-} in disable mode, but this is compatible with common video signal levels. In disabled state the output can withstand about 1000 V/ μ s slew rate signals impressed on it without the output transistors turning on.

The /Disable pin logic level is referred to V+. With $\pm 5V$ supplies, a CMOS or TTL driver with pull-up resistor will suffice. $\pm 15V$ supplies require a $\pm 14/\pm 11V$ drive span, or $\pm 15/\pm 10V$ nominally. Open-collector TTL with a tapped pull-up resistor can provide these spans. The impedance of the divider should be 1k or less for optimum enable/disable speed.

The EL2120C enables in 50 ns or less. When V_{IN} = 0, only a small switching glitch occurs at the output. When V_{IN} is some other value, the output overshoots by about 0.7V when settling toward its new enabled value.

Applications Information - Contd.

When the EL2120C disables, it turns off very rapidly for inputs of $\pm 1V$ or less, and the output sags more slowly for inputs larger than this. For inputs as large as $\pm 2.5V$ the output current can be absorbed by another EL2120C simultaneously enabled. Under these conditions, switching will be properly completed in 50 ns or less.

The greater thermal resistance of the SO-8 package requires that the EL2120C be operated from $\pm 10V$ supplies or less to maintain the 150°C maximum die temperature over the commercial temperature range. The P-DIP package allows the full $\pm 16.5V$ supply operation.

The EL2120C Macromodel

This macromodel has been developed to assist the user in simulating the EL2120C with surrounding circuitry. It was developed for the PSPICE simulator (copywritten by the Microsim corporation), and may need to be rearranged for other simulators, particularly the H operator. It approximates frequency response and small-signal transients as well, although the effects of load capacitance does not show. This model is slightly more complicated than the models used for low-frequency op-amps, but is much more accurate for AC.

The model does not simulate these characteristics accurately:

noise	non-linearities
slew rate limitations	temperature effects
settling time	manufacturing variations
input or output resonances	CMRR and PSRR
