

## SG2525A SG3525A

### **REGULATING PULSE WIDTH MODULATORS**

- 8 TO 35 V OPERATION
- 5.1 V REFERENCE TRIMMED TO ± 1 %
- 100 Hz TO 500 KHz OSCILLATOR RANGE
- SEPARATE OSCILLATOR SYNC TERMINAL
- ADJUSTABLE DEADTIME CONTROL
- INTERNAL SOFT-START
- PULSE-BY-PULSE SHUTDOWN
- INPUT UNDERVOLTAGE LOCKOUT WITH HYSTERESIS
- LATCHING PWM TO PREVENT MULTIPLE PULSES
- DUAL SOURCE/SINK OUTPUT DRIVERS

#### DESCRIPTION

The SG3525A series of pulse width modulator integrated circuits are designed to offer improved performance and lowered external parts count when used in designing all types of switching power supplies. The on-chip + 5.1 V reference is trimmed to  $\pm$ 1 % and the input common-mode range of the error amplifier includes the reference voltage eliminating external resistors. A sync input to the oscillator allows multiple units to be slaved or a single unit to be synchronized to an external system clock. A single resistor between the  $C_T$  and the discharge terminals provide a wide range of dead time ad- justment. These devices also feature built-in soft-start circuitry with only an external timing capacitor required. A shutdown terminal controls both the soft-start circuity and the output stages, providing instantaneous

turn off through the PWM latch with pulsed shutdown, as well as soft-start recycle with longer shutdown commands. These functions are also controlled by an undervoltagelockout which keeps the outputs off and the soft-start capacitor discharged for sub-normal input voltages. This lockout circuitry includes approximately 500 mV of hysteresis for jitterfree operation. Another feature of these PWM circuits is a latch following the comparator. Once a PWM pulses has been terminated for any reason, the outputs will remain off for the duration of the period. The latch is reset with each clock pulse. The output stages are totem-pole designs capable of sourcing or sinking in excess of 200 mA. The SG3525A output stage features NOR logic, giving a LOW output for an OFF state.

#### ELECTRICAL CHARACTERISTICS (continued)

These parameters, although guaranteed over the recommended operating conditions, are not 100 % tested in production.

Tested at  $f_{OSC} = 40 \text{ KHz}$  (RT = 3.6 K $\Omega$ , CT = 10nF, RD = 0  $\Omega$ ). Approximate oscillator frequency is defined by : WW.100Y.COM

1 f = C<sub>T</sub>(0.7 R<sub>T</sub>+3 R<sub>D</sub>)

DC transconductance (g<sub>M</sub>) relates to DC open-loop voltage gain (G<sub>v</sub>) according to the following equation : G<sub>v</sub> = g<sub>M</sub> R<sub>L</sub> where R<sub>L</sub> is the resistance from pin 9 to ground. The minimum g<sub>M</sub> specification is used to calculate minimum G<sub>V</sub> when the error amplifier output is loaded. WWW.100Y.COM. WWW.100Y.COM

#### RECOMMENDED OPERATING CONDITIONS (•)

Parameter	Value
Input Voltage (Vi)	8 to 35 V
Collector Supply Voltage (V <sub>C</sub> )	4.5 to 35 V
Sink/Source Load Current (steady state)	0 to 100 mA
Sink/Source Load Current (peak)	0 to 400 mA
Reference Load Current	0 to 20 mA
Oscillator Frequency Range	100 Hz to 400 KHz
Oscillator Timing Resistor	2 KΩ to 150 KΩ
Oscillator Timing Capacitor	0.001 μF to 0.1 μF
Dead Time Resistor Range	0 to 500 Ω

Figure 4 : Error Amplifier Voltage Gain and Phase vs. Frequency.

#### **PRINCIPLES OF OPERATION**

SHUTDOWN OPTIONS (see Block Diagram)

Since both the compensation and soft-start terminals (Pins 9 and 8) have current source pull-ups, either can readily accept a pull-down signal which only has to sink a maximum of  $100 \,\mu$ A to turn off the outputs. This is subject to the added requirement of discharging whatever external capacitance may be attached to these pins.

An alternate approach is the use of the shutdown circuitry of Pin 10 which has been improved to enhance the available shutdown options. Activating this circuit by applying a positive signal on Pin 10 performs two functions : the PWM latch is immediately set providing the fastest turn-off signal to the outputs ; and a 150  $\mu$ A current sink begins to discharge the external soft-start capacitor. If the shutdown command is short, the PWM signal is terminated without significant discharge of the soft-start capacitor, thus, allowing, for example, a convenient implementation of pulse-by-pulse current limiting. Holding Pin 10 high for a longer duration, however, will ultimately discharge this external capacitor, recycling slow turn-on upon release.

Pin 10 should not be left floating as noise pickup could conceivably interrupt normal operation.

Figure 7 : Output Circuit (1/2 circuit shown).

For single-ended supplies, the driver outputs are grounded. The  $V_C$  terminal is switched to ground by the totem-pole source transistors on alternate oscillator cycles.

Figure 10.

The low source impedance of the output drivers provides rapid charging of Power Mos input capacitance while minimizing external components.

#### SG2525A-SG3525A

In conventional push-pull bipolar designs, forward base drive is controlled by  $R_1 - R_3$ . Rapid turn-off times for the power devices are achieved with speed-up capacitors  $C_1$  and  $C_2$ .

#### Figure 11.

Low power transformers can be driven directly. Automaticreset occurs during dead time, when both ends of the primary winding are switched to ground.
