# WY.COM WW.100Y.COM.TW **TDA8702** 8-bit video digital-to-analog converter

Product specification Supersedes data of April 1993 File under Integrated Circuits, IC02

1996 Aug 23

WWW.100Y.COM.TW

**Philips** 

**Semiconductors** 

# TDA8702

#### FEATURES

- 8-bit resolution
- Conversion rate up to 30 MHz
- TTL input levels
- Internal reference voltage generator
- Two complementary analog voltage outputs
- No deglitching circuit required
- Internal input register
- Low power dissipation
- Internal 75 Ω output load (connected to the analog supply)
- Very few external components required.

#### APPLICATIONS

- High-speed digital-to-analog conversion
- Digital TV including:
  - field progressive scan
  - line progressive scan
- Subscriber TV decoders
- Satellite TV decoders
- Digital VCRs.

#### **GENERAL DESCRIPTION**

The TDA8702 is an 8-bit Digital-to-Analog Converter (DAC) for video and other applications. It converts the digital input signal into an analog voltage output at a maximum conversion rate of 30 MHz. No external reference voltage is required and all digital inputs are TTL compatible.

#### QUICK REFERENCE DATA

#### Note

- 1. D0 to D7 connected to  $V_{CCD}$  and CLK connected to DGND.
- The analog output voltages (V<sub>OUT</sub> and V<sub>OUT</sub>) are negative with respect to V<sub>CCA</sub> (see Table 1). The output resistance between V<sub>CCA</sub> and each of these outputs is typically 75 Ω.
- 3. The –3 dB analog output bandwidth is determined by real time analysis of the output transient at a maximum input code transition (code 0 to 255).

#### Note

- 1. D0 to D7 are connected to V<sub>CCD</sub>, CLK is connected to DGND.
- The analog output voltages (V<sub>OUT</sub> and V<sub>OUT</sub> are negative with respect to V<sub>CCA</sub> (see Table 1). The output resistance between V<sub>CCA</sub> and each of these outputs is 75  $\Omega$  (typ.).
- 3. The -3 dB analog output bandwidth is determined by real time analysis of the output transient at a maximum input code transition (code 0 to 255).
- 4. The worst case characteristics are obtained at the transition from input code 0 to 255 and if an external load impedance greater than 75  $\Omega$  is connected between V<sub>OUT</sub> or V<sub>OUT</sub> and V<sub>CCA</sub>. The specified values have been measured with an active probe between V<sub>OUT</sub> and AGND. No further load impedance between V<sub>OUT</sub> and AGND has been applied. All input data is latched at the rising edge of the clock. The output voltage remains stable (independent of input data variations) during the HIGH level of the clock (CLK = HIGH). During a LOW-to-HIGH transition of the clock (CLK = LOW), the DAC operates in the transparent mode (input data will be directly transferred to their corresponding analog output voltages (see Fig.5).
- 5. The data set-up (t<sub>SU:DAT</sub>) is the minimum period preceding the rising edge of the clock that the input data must be stable in order to be correctly registered. A negative set-up time indicates that the data may be initiated after the rising edge of the clock and still be recognized. The data hold time (t<sub>HD:DAT</sub>) is the minimum period following the rising edge of the clock that the input data must be stable in order to be correctly registered. A negative hold time indicates that the data may be released prior to the rising edge of the clock and still be recognized.
- 6. The definition of glitch energy and the measurement set-up are shown in Fig.6. The glitch energy is measured at the input transition between code 127 to 128 and on the falling edge of the clock.

#### SOLDERING

#### Introduction

There is no soldering method that is ideal for all IC packages. Wave soldering is often preferred when through-hole and surface mounted components are mixed on one printed-circuit board. However, wave soldering is not always suitable for surface mounted ICs, or for printed-circuits with high population densities. In these situations reflow soldering is often used.

This text gives a very brief insight to a complex technology. A more in-depth account of soldering ICs can be found in our *"IC Package Databook"* (order code 9398 652 90011).

#### DIP

SOLDERING BY DIPPING OR BY WAVE

The maximum permissible temperature of the solder is 260 °C; solder at this temperature must not be in contact with the joint for more than 5 seconds. The total contact time of successive solder waves must not exceed 5 seconds.

The device may be mounted up to the seating plane, but the temperature of the plastic body must not exceed the specified maximum storage temperature ( $T_{stg max}$ ). If the printed-circuit board has been pre-heated, forced cooling may be necessary immediately after soldering to keep the temperature within the permissible limit.

#### REPAIRING SOLDERED JOINTS

Apply a low voltage soldering iron (less than 24 V) to the lead(s) of the package, below the seating plane or not more than 2 mm above it. If the temperature of the soldering iron bit is less than 300 °C it may remain in contact for up to 10 seconds. If the bit temperature is between 300 and 400 °C, contact may be up to 5 seconds.

#### SO

#### **REFLOW SOLDERING**

Reflow soldering techniques are suitable for all SO packages.

Reflow soldering requires solder paste (a suspension of fine solder particles, flux and binding agent) to be applied to the printed-circuit board by screen printing, stencilling or pressure-syringe dispensing before package placement. Several techniques exist for reflowing; for example, thermal conduction by heated belt. Dwell times vary between 50 and 300 seconds depending on heating method. Typical reflow temperatures range from 215 to 250 °C.

Preheating is necessary to dry the paste and evaporate the binding agent. Preheating duration: 45 minutes at 45  $^{\circ}$ C.

#### WAVE SOLDERING

Wave soldering techniques can be used for all SO packages if the following conditions are observed:

- A double-wave (a turbulent wave with high upward pressure followed by a smooth laminar wave) soldering technique should be used.
- The longitudinal axis of the package footprint must be parallel to the solder flow.
- The package footprint must incorporate solder thieves at the downstream end.

During placement and before soldering, the package must be fixed with a droplet of adhesive. The adhesive can be applied by screen printing, pin transfer or syringe dispensing. The package can be soldered after the adhesive is cured.

Maximum permissible solder temperature is 260 °C, and maximum duration of package immersion in solder is 10 seconds, if cooled to less than 150 °C within 6 seconds. Typical dwell time is 4 seconds at 250 °C.

A mildly-activated flux will eliminate the need for removal of corrosive residues in most applications.

#### REPAIRING SOLDERED JOINTS

Fix the component by first soldering two diagonallyopposite end leads. Use only a low voltage soldering iron (less than 24 V) applied to the flat part of the lead. Contact time must be limited to 10 seconds at up to 300 °C. When using a dedicated tool, all other leads can be soldered in one operation within 2 to 5 seconds between 270 and 320 °C.
